Half dose of prostaglandin F2α is effective to induce luteolysis in the synchronization of ovulation protocol for fixed-time artificial insemination in buffalo (*Bubalus bubalis*)

Meia dose de prostaglandina F2α é eficaz na indução da luteólise em protocolos de sincronização da ovulação para inseminação artificial em tempo fixo em bubalinos (*Bubalus bubalis*)

---

**Summary**

The objective of this study was to evaluate the efficiency of half dose of PGF₂α in the synchronization of ovulation protocol (GnRH/PGF₂α/GnRH) for fixed-time artificial insemination in buffalo. Two hundred and sixty two buffaloes (*40 days postpartum*) were divided in 2 groups (Group 1, n = 125, GnRH/½ dose de PGF₂α/GnRH; Control Group, n = 137, GnRH/PGF₂α/GnRH). Animals in Group 1 received 25mg of GnRH IM (Lecirilin, Gestran-plus®) and, seven days later, half dose of PGF₂α IM (75mg d-cloprostenol, Prelolan®). Two days after PGF₂α injection, all animals received 25mg of GnRH IM (Lecirilin). Animals in Control Group received the same treatment, except for the dose of PGF₂α (150mg, IM, d-cloprostenol, Prelolan®). All animals were fixed-time inseminated 16 hours after the second GnRH injection. Blood samples were collected from 35 buffaloes in Group 1 and 30 buffaloes in Control Group on day of PGF₂α and second GnRH injections to measure plasma progesterone concentrations. Conception rate was not influenced by PGF₂α dosage (*P>0.05*). Conception rates were 48.00% (60/125) and 40.90% (56/137) in Group 1 and Control Group, respectively. It was observed that 88.60% (*n* = 35) of the buffaloes in Group 1 and 90.00% (*n* = 30) in Control Group presented luteolysis 48 hours after the PGF₂α injection (*P>0.05*). In summary, present data show that both treatments result in acceptable conception rates. Therefore, the recommended dose of PGF₂α can be reduced in 50.00% in the synchronization of ovulation protocol for fixed-time artificial insemination in buffalo.
Introduction

The efficiency of synchronization of ovulation for fixed-time artificial insemination in buffalo was previously studied\(^1\). Synchronization of follicle growth, as well as induction of ovulation with exogenous GnRH injections have resulted in satisfactory conception rates in fixed-time artificial insemination (TAI) programs in buffalo\(^2\).

GnRH injection, in any phase of the estrous cycle, results in a peak of LH that promotes the ovulation of follicles > 9.0 mm\(^3\) or luteinization of non-viable follicles and emergence of a new follicle wave 2 or 3 days later\(^4\). With ovulation or luteinization of the dominant follicle, progesterone levels remain high and therefore an injection of PGF\(_2\alpha\) is included on Day 7 of the protocol to induce luteolysis and allow the ovulation of the new dominant follicle\(^5\). The second GnRH injection is recommended 48 hours after PGF\(_2\alpha\) injection for better synchronization of ovulation and benefit TAI\(^6\).

Several studies have demonstrated the efficiency of these protocols for synchronization of ovulation using reduced doses of PGF\(_2\alpha\) in bovine\(^6\). Chohan\(^7\) verified that reduced doses of PGF\(_2\alpha\) promote luteolysis and induce estrus and ovulation in buffalo. Thus, the objective of this study was to assess the efficiency of half recommended dose of PGF\(_2\alpha\) in the synchronization of ovulation protocol for fixed time insemination in buffalo.

Material and Method

Animals

The experiment was performed in properties in southeast Brazil during the breeding season of 2001 (autumn and winter; BARUSELLI\(^8\)). Two hundred and sixty two multiparous dairy Murrah buffaloes were selected according to postpartum period (≥240 days) and body condition score (BCS ≥ 3.0; scale 1 to 5). All animals were maintained in pasture regime with mineral salt support.

Experimental Design

Animals in Group 1 (n = 125) received 25mg of GnRH IM (Lecirelin, Gestran-plus\(^®\)) on Day 0 and, seven days later (Day 7) 75mg of PGF\(_2\alpha\) IM (d-cloprostenol, Prelaban\(^®\)). Two days after PGF\(_2\alpha\) injection, these animals received 25mg of GnRH IM (Lecirelin). Animals in Control Group (n = 137) received the same treatment except for the dose of PGF\(_2\alpha\) that was twice higher (150mg, IM, d-cloprostenol, Prelaban\(^®\)). All animals were fixed-time inseminated 16 hours after the second GnRH injection in both groups (Figure 1).

To avoid influence of semen on conception rate, semen batches were randomly divided between groups. Furthermore all inseminations were performed by the same person to minimize influence on the results. Conception was checked by transrectal ultrasonography using a 5.0MHz probe (Pie Medical 480, Netherlands) 30 days after TAI.

Blood samples for hormonal analysis

At the moment of PGF\(_2\alpha\) (Day 7) and the second GnRH (Day 9) injections, blood samples were collected from jugular vein to measure plasma progesterone concentration in 35 buffaloes in Group 1 (75mg of d-cloprostenol, Prelaban\(^®\)); half dose of PGF\(_2\alpha\), and 30 buffaloes in Control Group (150mg of d-cloprostenol, recommended dose of PGF\(_2\alpha\)). Progesterone concentration was determinate by radioimmunoassay
(RIA) using a commercial kit (DPC, Diagnostic Products Corporation, USA). The sensitivity of the test was 0.05 ng/ml and an intra assay coefficient of variation was 8.00%.

**Statistical analysis**

Chi-square test was used to analyze the binomial variables, percentage of buffaloes with concentration of progesterone <1.0 ng/ml and conception rate. ANOVA was used to evaluate the continuous variables (progesterone concentration) for repeated measures. T-test was used to evaluate differences between means.

**Results**

Evidence of luteolysis was observed 48 hours after PGF₂ alpha injection in 88.60% (n = 35) of the buffaloes in Group 1 and 90.00% (n = 30) in Control Group (P > 0.05; Table 1, Figure 2). Four animals (11.40%) in Group 1 and three (10.00%) in Control Group did not show decrease in progesterone concentration 48 hours after PGF₂ alpha injection (Figure 3).

Conception rate was not affected by the decreased in PGF₂ alpha dosage (P > 0.05). Conception rate in Group 1 and in Control Group were 48.00% (60/125) and 40.90% (56/137), respectively (Table 2).

The decrease in treatment cost for each pregnant buffalo treated with half dose of PGF₂ alpha was R$8.81 (Table 3).

*Number of pregnant buffaloes at ultrasonography evaluation 30 days after TAI.

*Estimated costs of hormones. Cost of R$3.30 for 25mg of Lecrelin and R$4.50 for 150mg of d-cloprostenol.

*Cost for pregnancy was calculated dividing the total cost with hormones by the number of pregnant animals. Value of American dollar/real in the day of budget (US$1.00 = R$2.50).

Discussion

An adequate conception rate using the TAI was achieved in both experimental groups. Conception rates of buffaloes inseminated did not differ between groups (Group 1 = 48.00% vs. Control Group = 40.90%, P > 0.05). These results are similar to those obtained by Barros, who evaluated the use of half dose of PGF$_{2\alpha}$ in bovine synchronized with the protocol GnRH/PGF$_{2\alpha}$/BE and verified similar pregnancy rates when compared to animals treated with the full dose. Reduced doses of PGF$_{2\alpha}$ have been efficient to induce luteolysis, estrus and ovulation in buffalo as shown by Chohan.

The possibility to decrease the dose of PGF$_{2\alpha}$ without altering the efficiency of luteolysis contributes to reduce costs of the protocol for synchronization of the ovulation. PGF$_{2\alpha}$ injection represents a significant protocol cost. However, if reduction of PGF$_{2\alpha}$ dosage is not efficient to induce luteolysis, conception will not occur, even if animal ovulate.

In present study, luteolysis was hormonally verified in 88.60% of buffaloes in Group 1 and 90.00% in Control Group (P > 0.05). The luteolysis rate observed agreed with SANTOS et al. that worked with bovine synchronized by the “Ovsynch” protocol (GnRH/PGF$_{2\alpha}$/GnRH).

Present data allow to...
recommend half dose of PGF$_2$$_\alpha$ (d-cloprostenol) to efficiently induce luteolysis, without affecting conception rate of synchronization protocol for TAI. Half dose of PGF$_2$$_\alpha$ reduced treatment cost in R$8.81 for each pregnant buffalo. In summary, it was verified that half dose of PGF$_2$$_\alpha$ is enough to induce luteolysis in synchronization of ovulation protocol for fixed-time artificial insemination in buffalo.

Resumo

O objetivo desse estudo foi avaliar a eficiência da meia dose de PGF$_2$$_\alpha$ no protocolo de sincronização da ovulação (GnRH/PGF$_2$$_\alpha$/GnRH) para inseminação artificial em tempo fixo em bubalinos. Foram utilizadas 262 búfalas (40 dias pós-parto), divididas em dois grupos (Grupo 1, n = 125, GnRH/1/2 dose de PGF$_2$$_\alpha$/GnRH; Grupo Controle, n = 137, GnRH/PGF$_2$$_\alpha$/GnRH). Os animais do Grupo 1 receberam 25 mg de GnRH IM (Lecirelina, Gestran-plus®) e, após sete dias, receberam 75 mg de PGF$_2$$_\alpha$ IM (d-cloprostenol, Preloban®). Dois dias após a aplicação da PGF$_2$$_\alpha$, esses animais receberam 25 mg de GnRH IM (Lecirelina). Os animais do Grupo Controle receberam o mesmo tratamento, à exceção da dose de PGF$_2$$_\alpha$ (150 mg de d-cloprostenol, Preloban®). Todos os animais foram inseminados em tempo fixo 16 horas após a segunda aplicação de GnRH. Foram colhidas amostras de sangue de 35 búfalas do Grupo 1 e de 30 do Grupo Controle nos dias da aplicação de PGF$_2$$_\alpha$ e da segunda dose de GnRH. As colheitas de sangue foram realizadas para avaliar as concentrações plasmáticas de progestásterona. Os resultados demonstraram que a taxa de concepção não foi influenciada pela dose de PGF$_2$$_\alpha$. As taxas de concepção dos Grupos 1 e Controle foram de 48,00% (60/125) e 40,90% (56/137), respectivamente. Observou-se que 88,60% (n = 35) das búfalas do Grupo 1 e 90,00% (n = 30) do Grupo Controle apresentaram luteolise 48 horas após a aplicação de PGF$_2$$_\alpha$. Em conclusão, os resultados indicaram que ambos tratamentos proporcionaram aceitáveis taxas de concepção. Dessa forma, a dose recomendada de PGF$_2$$_\alpha$ pode ser reduzida pela metade no protocolo de sincronização da ovulação para inseminação artificial em tempo fixo em bubalinos.
