Abstract. Over the last few decades, the systematics and evolution of carcharodontosaurids, a group of large predatory dinosaurs, from North Africa have been better understood mainly due the discovery of new species. We review this record here and discuss its importance for understanding the evolution and ecology of these dinosaurs. North Africa has one of the best records of carcharodontosaurid species. These species show dietary specializations and paleogeographic distributions similar to other top predatory theropods such as Abelisauridae and Spinosauridae. However, carcharodontosaurids have a wider distribution than other large theropods. The middle Cretaceous of North Africa was characterized by the niche overlap between large predators. This evidence increases our understanding of the evolution of Carcharodontosauridae in a highly competitive region, a conjuncture rarely reported for large top predators.

Key-Words. Carcharodontosauridae; Gondwana; Middle Cretaceous; North Africa; Overlap.

INTRODUCTION

Several species of predatory dinosaurs are grouped in the family Carcharodontosauridae, a subgroup of basal tetanuran allosauroid theropods closely related to the well-known *Allosaurus* (Brusatte & Sereno, 2008; Benson *et al.*, 2010; Carrano *et al.*, 2012). Some of these species are among the largest theropods to ever live, with *Carcharodontosaurus*, *Giganotosaurus*, and *Acrocanthosaurus* approaching the famous *Tyrannosaurus rex* in size (*ca.* 12 meters in total body length, 3+ tons in mass: Benson *et al.*, 2014). Carcharodontosauridae had its main evolutionary radiation during the Early Cretaceous in Gondwana, but also has been recorded in some areas of Laurasia (*e.g.*, *Acrocanthosaurus*, *Concavenator*, *Shaochilong*, *Kelmaysaurus*). This cosmopolitan distribution differs from the more limited distribution of some other large theropods, particularly tyrannosaurids, which were restricted to the North America and Asia (*e.g.*, Holtz, 2004; Brusatte *et al.*, 2010a). During the early to middle part of the Cretaceous, carcharodontosaurids were among the most important large-bodied predatory dinosaurs globally, and were apex predators in many terrestrial ecosystems.

During the Early Cretaceous (late Aptian-Cenomanian), carcharodontosaurids were diverse and widespread in South American and Africa, particularly the northern parts of Africa that are now covered by the Sahara Desert. These Gondwanan carcharodontosaurids occupied the same areas as two other groups of large theropods, the sail-backed spinosauroids and the short-faced and small-armed abelisauroids. Indeed, fossils of these three groups are often found together (*e.g.*, Medeiros & Schultz, 2002; Brusatte & Sereno, 2007; Sereno & Brusatte, 2008). The diversity of carcharodontosaurids begins to decrease sometime during or after the Cenomanian, and no unequivocal fossils of the group have yet been found in the post-Cenomanian deposits of Gondwana. It appears, therefore, as if carcharodontosaurids went extinct in Gondwana by the Turonian, replaced by other large predatory dinosaurs such as megaraptorids and abelisaurids (Novas *et al.*, 2013). They apparently persisted longer in Laurasia, as the Chinese *Shaochilong* dates to the Turonian (Brusatte *et al.*, 2009), but sometime during the early-middle Late Cretaceous they were replaced as apex predators in North America and Asia by tyrannosaurids (Brusatte *et al.*, 2009, 2010a; Zanno & Makovicky, 2013).

Diet composition and environmental habitat

Carcharodontosaurids possessed generally tall and short skulls, a feature shared with most large theropods, but differing from the more elongate skulls of tyrannosaurids and the shorter and deeper skulls of abelisaurids. All of these theropods, however, had a carnivorous diet that included dinosaurs and other vertebrates (*e.g.*, Lü *et al.*, 2014). Along with the North African spinosaurids, carcharodontosaurids and abelisaurids are recorded in portions of the continent with marine influence and records of a diverse terrestrial and aquatic fauna.

Spinosauridae is a group of large-to-supersized theropod dinosaurs found in Africa, Asia, Europe, and South America (Stromer, 1915; Buffetaut & Ingavat, 1986; Charig & Milner, 1986; Sereno *et al.*, 1998; Ibrahim *et al.*, 2014). These dinosaurs have an elongated skull, subconical teeth, and dorsally displaced nostrils (Sereno *et al.*, 1998). This morphology gives unique characteristics to this group, similar in many ways to modern crocodylians such as gavials (*e.g.*, Cuff & Rayfield, 2013). Many studies show that the Spinosauridae had a piscivorous diet (Charig & Milner, 1986; Kitchener, 1987; Sereno *et al.*, 1998; Rayfield *et al.*, 2007; Milner, 2003; Amiot *et al.*, 2010; Ibrahim *et al.*, 2014). Nevertheless, evidence suggest that the spinosaurids were not exclusively piscivorous, but also fed on other tetrapods (Charig & Milner, 1997; Gatesy & Amato, 2008; Buffetaut *et al.*, 2004; Kellner, 2004).

Carcharodontosauridae species from the Cretaceous of North Africa

Species: *Carcharodontosaurus saharicus* Stromer, 1931.

Body size: Estimated between 12 and 13 meters long.

Distribution and geological unit: Algeria – Continental intercalaire; Egypt – Bahariya Formation, Mut Formation; Morocco – Aoufous Formation, Kem Kem Formation; Niger – Continental intercalaire Formation, Echkar Formation, Elrhaz Formation; Tunisia – Chenini Formation, Continental intercalaire Formation (see Carrano *et al.*, 2012 and Candeiro, 2015 all references herein).

Geochronology: Albian-Cenomanian.

General characteristics: *Carcharodontosaurus* was a colossal theropod dinosaur, estimated at over 12 meters in length and around 3 tons in body mass (Benson *et al.*, 2014). It had a huge skull that was over 1.5 meters long, and clearly was an apex predator. Many studies (Dal Sasso *et al.*, 2009; Eddy & Clarke, 2011) have argued that *C. saharicus* was possibly larger than the great *Tyrannosaurus rex*, but smaller than *Spinosaurus aegyptiacus*, which is found in the same layers as *Carcharodontosaurus*. The first material of *Carcharodontosaurus saharicus* was two teeth from Algeria described by Depéret & Savornin (1927). Better material was discovered in Egypt and described by Stromer (1931), but was unfortunately destroyed during an allied bombing raid in Munich during World

War II (Nothdurft *et al.*, 2002). This dinosaur remained poorly known until the discovery of a nearly complete new skull in Morocco, described by Sereno *et al.* (1996).

Species: *Carcharodontosaurus iguidensis* Sereno & Brusatte, 2007.

Body size: Estimated at between 12 and 13 meters long, based on the similar size of corresponding bones (*e.g.*, maxilla) between it and the better known and closely related *Carcharodontosaurus saharicus*.

Distribution and geological unit: Niger, Echkar Formation.

Geochronology: Cenomanian.

General characteristics: This second species of *Carcharodontosaurus* was discovered on an expedition to Niger, led by Paul Sereno of the University of Chicago. It is known from several parts of the skull, including a maxilla, part of a lacrimal, a well-preserved braincase and posterior skull roof, and several teeth. These bones are generally similar in size and shape to those of *Carcharodontosaurus saharicus*, but lack numerous autapomorphies of *C. saharicus* and possess their own unique characters. As a result, Brusatte & Sereno (2007) named this taxon as a new species of *Carcharodontosaurus*. They suggested that the presence of different species of this colossal theropod genus at generally the same time in Niger and Morocco may have been related to faunal differentiation, caused by shallow continental seas acting as barriers and isolating different parts of North Africa from each other.

Species: *Eocarcharia dinops* Sereno & Brusatte, 2008.

Body size: Approximately between 6 and 8 meters long.

Distribution and geological unit: Niger, Elrhaz Formation.

Geochronology: Aptian-Albian.

General characteristics: *Eocarcharia* is a more basal carcharodontosaurid than *Carcharodontosaurus*, and is also several million years older. Like other carcharodontosaurids, it had a large bony 'brow' on the postorbital bone, above the orbit. This brow was heavily textured by vascular grooves and probably was covered by keratin in life (Sereno & Brusatte, 2008).

Species: *Sauroniops pachytholus* Cau, Dalla-Vecchia & Fabbri, 2012.

Body size: Unknown. Estimated by Cau *et al.* (2012) as 10-12 meters long, approximately the same size as *Carcharodontosaurus*.

Distribution and geological unit: Morocco, Kem Kem beds (Ifezouane Formation).

Geochronology: Cenomanian.

General characteristics: The carcharodontosaurid *Sauroniops pachytholus* is known only from a single frontal, which was sold by a commercial dealer to a museum in Italy, but was argued to have most probably come from the Kem Kem beds. This bone differs from the frontals of other carcharodontosaurids in having a prominent bony dome on the dorsal surface of the frontal. This feature inspired this taxon's generic name: Sauron (Eye of Sauron) is a reference to the expressive eye on the top of a tower which represents Sauron, considered the main villain of the Lord of the Rings trilogy (see Cau et al., 2012). If the provenance information for this specimen is correct, it is found in the same layers as other large theropod dinosaurs – such as *Deltadromeus* and *Spinosaurus*. The phylogenetic relationships of this taxon are difficult to pin down because of the highly fragmentary material, but the cladistic analysis of Cau et al. (2012) found *Sauroniops* to group with *Eocarcharia* in a clade of basal carcharodontosaurids.

DISCUSSION

Temporal and geographic distribution

Over the last two decades, the discovery of many new fossils has revolutionized our understanding of carcharodontosaurid anatomy, distribution, phylogeny, and evolution, clarifying what was formerly a very poorly known group of large carnivorous dinosaurs. Many of these discoveries come from northern Africa, showing that this region was an important center of carcharodontosaurid evolution during the middle part of the Cretaceous.

The first diagnostic fossils of carcharodontosaurids come from the Late Jurassic of Africa (*Veterupristisaurus milneri* Rauhut, 2011 and other specimens reviewed therein), and over the next several tens of millions of years this group diversified and spread around the world. They achieved a cosmopolitan distribution, with many species recorded in Gondwana (particularly North Africa and South America), but also in Europe (*Concavenator*), Asia (*Kelmaysaurus*, *Shaochilong*), and North America (*Acrocanthosaurus*). Currently, there are more species of carcharodontosaurids known from North Africa (four) than any other part of the world.

In North Africa, the Carcharodontosauridae shared habitats with the large abelisaurids (*Rugops*, *Kryptops*) and spinosaurids (*Suchomimus*, *Spinosaurus*), forming a common triumvirate of large theropods (e.g., Brusatte & Sereno, 2007; Sereno & Brusatte, 2008) (Fig. 2). This triumvirate apparently persisted for a long period of time, as it is known from various formations of multiple ages (e.g., Aptian-Albian Elrhaz Formation, Cenomanian Echkar Formation, Cenomanian 'Kem Kem beds'). Thus, these predators could have competed due niche overlap, or their coexistence could be explained by niche partitioning. In fact, there are many records of dinosaur species found in the same layers that yield the large theropods

of North Africa. These regions seem to have been particularly diverse, which may be explained by the paleogeography of the area. During the Aptian-Cenomanian many episodes of sea regression occurred, resulting in the formation of land connections between Africa-South America-Asia. These land connections may have allowed the terrestrial migration of Carcharodontosauridae (Sereno et al., 1996) and of other cosmopolitan tetrapods of the middle Cretaceous (e.g., Krause et al., 1997; Rauhut, 1999; Sues et al., 2002; Naish et al., 2004; Machado & Kellner, 2005; Cavin et al., 2010; Lindoso et al., 2012; McFeeters et al., 2013; Fanti, 2009, 2012; Candeiro et al., 2011, Candeiro, 2015).

The presence of Carcharodontosauridae in the middle Cretaceous of North Africa shows that it is necessary to make a detailed biogeographic analysis of this period. However, the close relationship between *Carcharodontosaurus saharicus*, *C. iguidensis*, *Eocarcharia dinops*, and *Sauroniops pachytholus* with the South American carcharodontosaurids *Giganotosaurus carolinii* and *Mapusaurus chubutensis*, as well as the presence of carcharodontosaurids in North America, Europe, and Asia, reinforce the hypothesis of faunal interchange between the northern and southern continents during the middle Cretaceous (e.g., Brusatte, et al., 2009, 2010b and references therein; Candeiro, 2015). Indeed, there is growing evidence that many (but not all) dinosaur groups had a wide distribution during the Early to middle part of the Cretaceous, before faunas became more differentiated (provincial) in the Late Cretaceous, when the continents were widely separated (e.g., Brusatte et al., 2009, 2010b and references therein). However, the two other clades of large-bodied predators, Abelisauroidea and Spinosauridae, do not have such a widespread distribution as Carcharodontosauridae during the Early-middle Cretaceous, at least based on the currently known fossil record.

There are many possibilities to explain the pattern observed for the wide distribution of Carcharodontosauridae, which was marked during the middle Cretaceous. Although the rupture of Pangea occurred before this period, the faunal interchange of tetrapods during the Early-middle Cretaceous was made through several dispersal corridors. For example, the trans-Turgai connection was a corridor where faunal interchange between the northern and southern continents possibly occurred. During the middle Cretaceous, Europe was connected to Asia, and closely located to Northern Gondwana (Smith et al., 1994).

Niche overlap

In a biogeographical context, the Carcharodontosauridae from the middle Cretaceous of Africa are very interesting, as this region had a complex geological history during the fragmentation of Gondwana (Chen et al., 1993; Metcalfe, 2006). There is also growing evidence that parts northern South America (e.g., Araripe, Parnaíba, and São Luis basins) were inhabited by many of the same groups of dinosaurs as northern Africa during

this time, including herbivorous species (rebbachisaurids, diplodocids, titanosaurids) and theropods (abelisaurids, neovenatorids, spinosaurids) (Candeiro, 2015). Future discoveries will help to test just how strong this biogeographic linkage was between the two regions during this time, and whether they were more closely linked to each other (in terms of shared faunas) than to other parts of the globe.

Carcharodontosaurids, abelisaurids, and spinosaurids seem to have had very similar diets, which included other tetrapods, and also fish for spinosaurids (Fig. 3). The consumption of tetrapods (especially other dinosaurs) was surely important to these often giant terrestrial predators. The major question is: how did these multiple groups of large predators co-exist with each other? There are several possibilities, which are difficult to test,

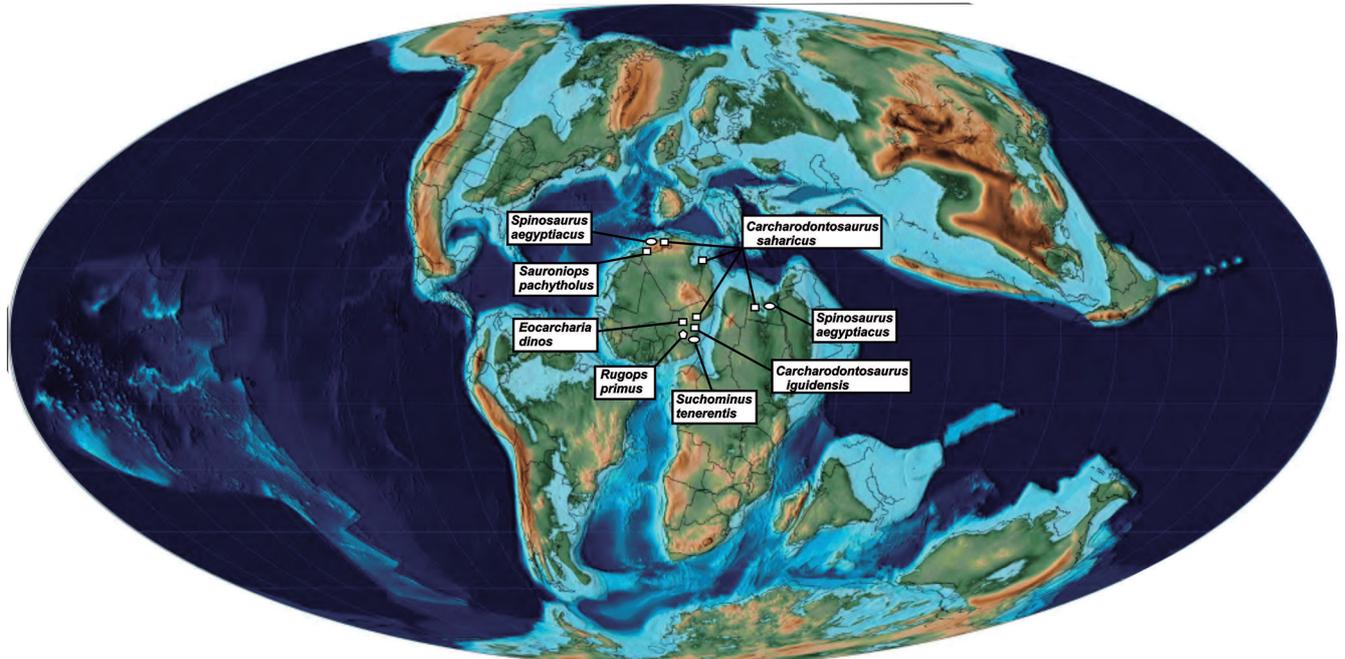

Figure 2. North African geographical distribution of the carcharodontosaurids, abelisaurids and spinosaurids during middle Cretaceous. Maps copyright CR Scotese Paleomap.

but which can be the subject of future work. It may be that these groups ate slightly different prey, and in this sense the fish-eating habits of spinosaurids may have been particularly important to differentiate them from other large theropods. Or it could be that these large theropods hunted at different times (e.g., day vs. night), in slightly different habitats (e.g., forest vs. open plains), or in the style they hunted (e.g., pursuit vs. ambush). Or there could be other explanations. Whatever the reason, it is clear that these large theropods must have found a way to successfully live in the same faunas while eating generally similar foods, because all three groups were diverse and had great evolutionary success during the Early-middle Cretaceous.

CONCLUDING REMARKS

Carcharodontosaurids were some of the largest predatory dinosaurs to ever live. For many decades there were a mysterious group, represented by only a handful of fossils, but recent discoveries have revolutionized our understanding of their anatomy, systematics, phylogeny, biogeography, and evolution. The best record of carcharodontosaurids comes from northern Africa, where four species have been discovered. We reviewed this record and discussed how it shows that carcharodontosaurids were part of a general cosmopolitan dinosaur fauna that was globally distributed during the Early-middle Cretaceous, with particular affinities with South American taxa. We discussed how physical geography affected the evolution of carcharodontosaurids, particularly the slow fragmentation of Western Gondwana and its separation from Europe during the middle Cretaceous, and the waxing and waning of seaways that fragmented northern Africa into distinct provinces. We also noted how carcharodontosaurids are regularly found alongside fossils of two other types of giant theropods, spinosaurids and abelisaurids, and flagged several possible explanations for how these taxa could coexist while seemingly eating similar types of food. This review summarizes the state of knowledge on northern African carcharodontosaurids as it currently stands, and raises suggestions for future work that may help us better understand the evolutionary history of these fascinating dinosaurs.

ACKNOWLEDGMENTS

Brusatte is funded by a Marie Curie Career Integration Grant (EC 630652) and the University of Edinburgh. He thanks his former undergraduate mentor, Paul Sereno, for inviting him to work on what would become *Carcharodontosaurus iguidensis*, and sparking an interest in carcharodontosaurids. Thank to CR Scotese for paleomap authorization. This contribution was partially supported by the Conselho Nacional de Ciencia e Tecnologia Candeiro by Produtividade Pesquisa CNPq fellow.
